Technology/Practice Overview

Description

Low quality natural gas can lead to excessive filtration unit liquid recovery and transmission line cleanings at compressor stations. A partner has reported reducing methane and VOC emissions associated with these maintenance practices by requiring improvements in the quality of gas received from producers.

To enact a methane quality improvement, the operator obtained revised gas processing and compression agreements requiring reduced levels of gas contaminants such as particulates, water and gas liquids. This limited the amount of emissions associated with the gas filtration system operation, in particular, methane emissions from gas liquids storage tanks.

Methane Savings

500 Mcf/yr

Costs

Capital Costs (including installation)

None

Operating and Maintenance Costs (Annual)

☐ < $100 ■ $100-$1,000 ☐ > $1,000

Payback (Years)

☐ 0-1 ☐ 1-3 ■ 3-10 ☐ > 10

Principal Benefits

Reducing methane emissions was:

☐ **A primary justification for the project** ■ **An associated benefit of the project**

Operating Requirements

The implementation of this practice requires a new agreement between the gas producer and the transporter or enforcement of existing gas quality specifications.

Applicability

Any compressor facility directly receiving production gas and experiencing excessive liquids filtration, line pigging or receiving natural gas of lower than desired quality may benefit from improving their gas quality specifications.

Methane Emission Reductions

Methane emissions occur due to the venting of filtration liquid atmospheric storage tanks. One partner has reported methane reductions of over 500 Mcf for one year.

Economic Analysis

Basis for Costs and Savings

Methane emission reductions of 500 Mcf/yr is based on partner reported saving in a 600 psig system.

Discussion

Facility maintenance costs and reduced VOC emissions will be lower with reduced liquid loading on the filtration unit. Methane savings are significant, but not a primary justification.
